1 Generated query on insider

Step 1, per transaction: m = `AVG(shortintrt)` over its sentiment snapshots
Step 2, per order type: baseline v = `AVG(`m`)` ← the edited step
Step 3: ratio m/v per transaction; the ten largest

2 The choice, as an SQL edit

A: average of transaction means, `AVG(`m`)`; each transaction counts once

B: average over snapshots, `AVG(shortintrt)`; each snapshot counts once

all 10 output rows differ; e.g. IT183513: ratio 2.04796 (A) vs 2.05000 (B)

3 Benchmark example of the same type

BIRD, california_schools: "Which active district has the highest average score in Reading?" Rank districts by their best school's score, or by the average over their schools? (aggregation level)

4 Three requests (only the phrase that differs)

Specific, A: "average of the per-transaction averages (each transaction counted once)"

Specific, B: "over all matched sentiment snapshots (each snapshot counted once)"

Open: "the average short interest for its order type mix"

5 Checks passed

✓ no requirement lost or changed in any request (code and two reviewer models)
✓ each specific request accepted only for its own reading
✓ open request accepted for both readings by both reviewers
